

# CSCI 3150 Introduction to Operating Systems

LAB Three: Superblock – Define File system metadata

TA: CHEN Zizhan

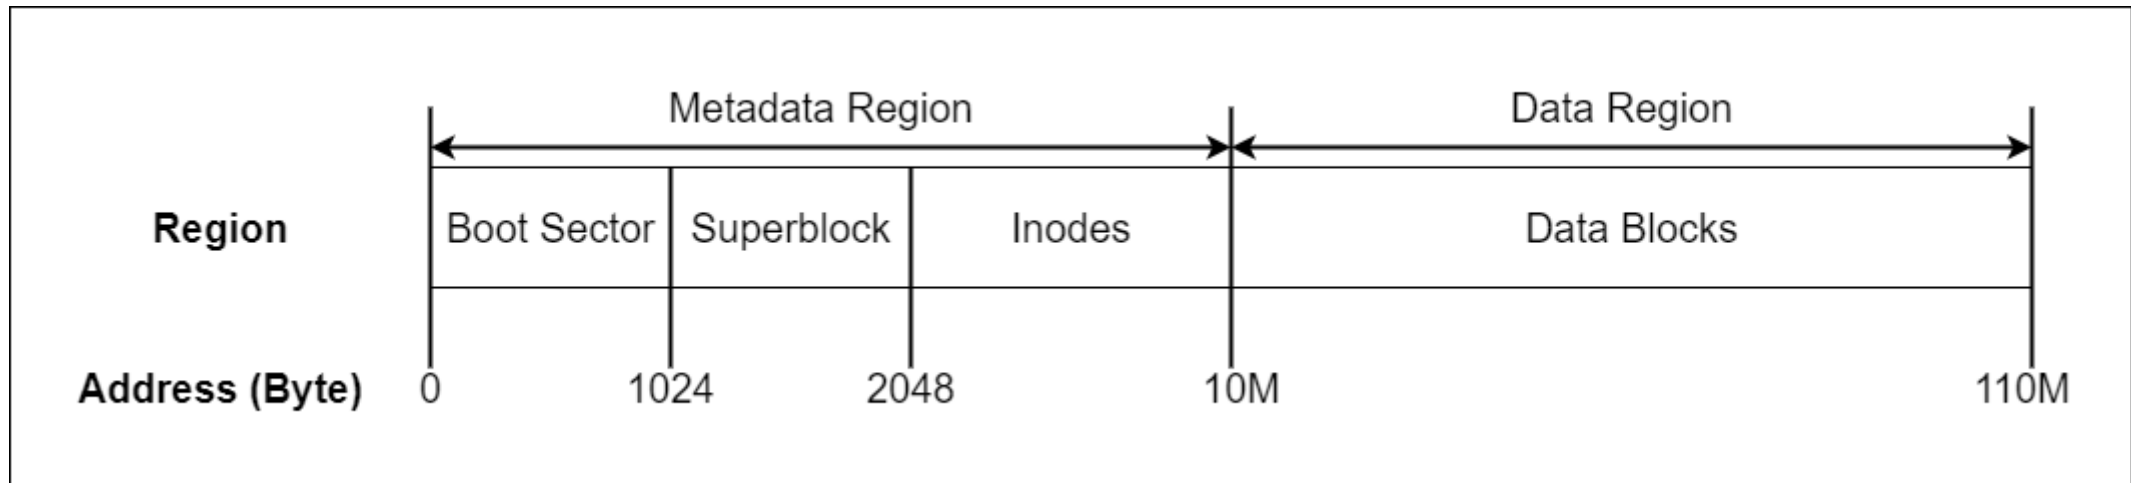

[chenzz@cse.cuhk.edu.hk](mailto:chenzz@cse.cuhk.edu.hk)

# Goal

- In the Project, you will be asked to implement some basic functions of a Simple File System.
- These two labs (lab-3 & 4) are the pre-knowledges to help you understand the project.

# Background

- File system can be divided into metadata region and data region.
- Superblock is the first block in the metadata region, which describes the basic information of the file system.
  - Where the inodes and data block begins
  - Block size

# Superblock structure

- A typical superblock structure can be found below:

```
typedef struct _super_block_  
{  
    int i_offset; /* the starting position of inode */  
    int d_offset; /* the starting position of data blocks */  
    int max_inode; /* the maximum number of inodes */  
    int max_data_blk; /* the maximum number of data blocks */  
    int next_available_inode; /* the index of next free inode */  
    int next_available_blk; /* the index of next free data block */  
    int blk_size; /* the size of data block */  
};
```

# Superblock parameters

- Specifically, in SFS (the simplified file system in project):
  - the inode region starts at 2048 bytes (i\_offset);
  - the data region starts at 10 MB (d\_offset);
  - the block size is 4 KB (blk\_size).

# Superblock parameters

- Some related parameters can be found below:

```
#define SB_OFFSET 1024 /* The offset of superblock region */  
#define I_OFFSET 2048 /* The offset of inode region */  
#define D_OFFSET 10485760 /* The offset of data region */  
#define MAX_INODE 100 /* The maximum number of inode */  
#define MAX_DATA_BLK 25600 /* The maximum number of block */  
#define BLK_SIZE 4096 /* The size per block */
```

# Get the metadata of a file system

- When we access a file system, the first step is reading the superblock region on the hard disk, load the superblock data into memory.
- From superblock we get the basic information of the file system, and access the files base on these basic information.
  - Read a file
  - Open a file

## Superblock.c -- A simple program to display the Superblock

- A simple program (superblock.c) has been provided to display the superblock. There are several files in the zip file:
  - **HD**: It is used to simulate the hard disk. This “HD” file has been properly initialized based on the data structure defined by `_super_block_` with the parameters above.
  - ***Superblock.h***: It contains the structure of superblock and the parameters of the SFS.
  - ***Superblock.c***: The C program with functions to read the superblock.
  - ***Superblock-test.c***: It contains two cases which show the superblock region on the hard disk and its information, respectively.

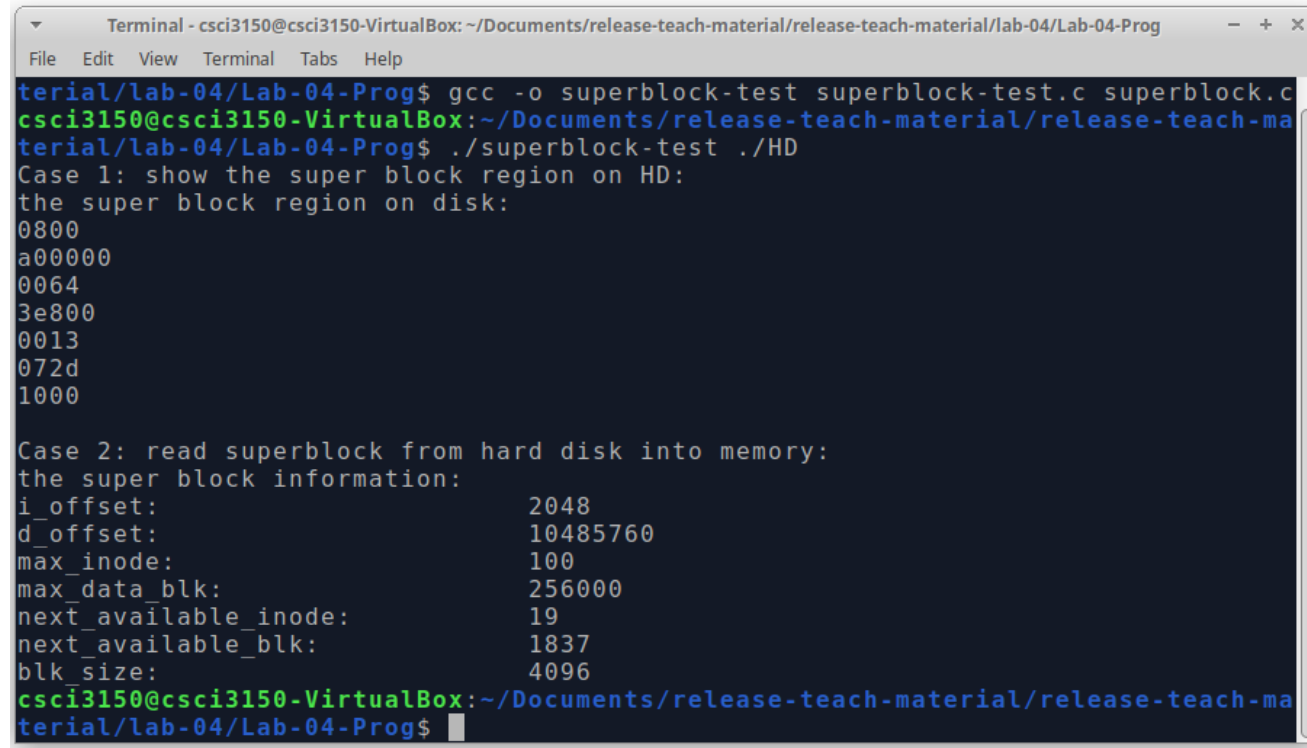

# Compile and Run

- Copy the **HD**, **superblock.c**, **superblock-test.c**, and **superblock.h** to your current directory.
- Compile the **superblock-test.c** as below:
- **gcc -o superblock-test superblock-test.c superblock.c**
- Then you can run the test program by:
- **./superblock-test ./HD**

# Result

- You can find two test cases shown like the figure below:

```
Terminal - csci3150@csci3150-VirtualBox: ~/Documents/release-teach-material/release-teach-material/lab-04/Lab-04-Prog
File Edit View Terminal Tabs Help
terial/lab-04/Lab-04-Prog$ gcc -o superblock-test superblock-test.c superblock.c
csci3150@csci3150-VirtualBox:~/Documents/release-teach-material/release-teach-material/lab-04/Lab-04-Prog$ ./superblock-test ./HD
Case 1: show the super block region on HD:
the super block region on disk:
0800
a00000
0064
3e800
0013
072d
1000

Case 2: read superblock from hard disk into memory:
the super block information:
i_offset:                2048
d_offset:                10485760
max_inode:                100
max_data_blk:            256000
next_available_inode:     19
next_available_blk:       1837
blk_size:                 4096
csci3150@csci3150-VirtualBox:~/Documents/release-teach-material/release-teach-material/lab-04/Lab-04-Prog$
```

# Implementation

- In **superblock.c** program, there is one main function:
- **read\_sb()**: read the superblock region into memory and form an entity of super block structure, then return the link of this entity.
- For more detailed implementation, please read the **superblock.c** program.
